

Morphometric analysis of pediments using GIS software and Python tools

Student Helper Project

We are looking for a student helper to help us extract morphometric information on pediments using GIS software and python tools. Pediments are very low relief, gently dipping erosive surfaces that are commonly found in cratonic areas in the vicinity of a high elevation feature such as an escarpment or a plateau. The data will be used to constrain a new model for the formation of pediments in Africa and other cratonic areas. The project is a collaboration between Jean Braun (GFZ Section Earth Surface Process Modelling) and Pierre Dietrich (Géosciences Rennes at University of Rennes and CNRS, France).

Candidates should send a mail to Jean Braun (jb Braun@gfz.de) with a short CV and a letter of motivation that compares their skills to the following required qualifications:

- very good knowledge of the use of GIS software (such as QGis)
- good Python programming skills
- ability to work in English
- being enrolled in a Master program in a German university

The position is for 1 day per week for an initial period of three months but could possibly be extended if needed.
